I don't know if this is appropriate because I'm new to newsgroups, however I am experiencing exactly the same problem to "anonymous".

I am using a Netgear FR114P which I had replaced under warranty as I was sure that it was the faulty item but I experienced the same problem with the replacement.

My ethernet is included with a Gigabyte GA-8KNXP MB and is a IntelPro 1000 CT

I find that as soon as the problem starts (approx 3-4 minutes after booting and internet connection is fine at that stage), if I go into network connections right click on the Intel LAC click repair once or twice it sometimes fixes the problem or disable and enable sometimes helps. I only have approx 30 seconds to do this as after that time the router port lights go out and then is a shutdown, power disconnection to the faulty computer, power reconnection and reboot.

Everything remains stable after the above is sorted for as long as the computer is operating 1 hour or 1 week

I have for a while used an SMC USB Ethernet Adapter Model SMC2206USB/ETH and this works flawlessly through the router however it does not suit me to keep using it.

Other computers on the system (running XP) have not experienced this problem and are not affected during this problem.

This is a bit vague but I think the problem has been there since new – appx 12 months

Any advice would be appreciated.
