> or Computer C?

You "log on to" Computer B or C by using ctrl – alt – del and putting in a username and password.

You connect to computer C or computer B, from computer A, by right clicking on my computer on Computer A and select "map network drive", select a drive letter and supply:

`\\computername\sharename`

Computername = the computername of Computer B or Computer C
Sharename = the folder you shared on Computer B or Computer C and gave *this* username (the username you logged onto computer A with) permission to use the folder.

When you set up the user on Computer B and C you have to share a folder, put files in it, and grant the user you created on Computer B and C, permission to use the shared resource. You should not be prompted for a username and password. That information is passed to Computer B or C when the connection is made. The account information passed to Computer B or C comes from the currently logged on account, of the connecting computer, in your case Computer A.
