Hoping someone can give me some helpful info. I have an HP Pavillion 754N. It has 512ram. I have 46.9 GB of hard drive space free. The PC has been running slowly in all applications, email , Internet, etc. When I bring up task

manager any function I do, search for a web page, bring up an email it shows

100% cpu and runs very slowly. I have defragged, I have deleted every old

program I could find, I have removed all profiles except mine and I completely removed that and added it back in for a fresh profile. I ran a

disk cleanup in windows and a disk clean in mcafee. I even went to HP's

website and ran their disk and memory checks, no errors found. I ran spybot

for spyware , I changed performance settings to adjust for best performance.

I am hoping someone out there has some other suggestions as my last option is

a complete restore which will take me hours to recover from Any suggestions

will be greatly appreciated

I have a similar problem CPU usage at 80%+ disk continually being accessed which affects performance. Feels like a virus we had three or so years ago but I have completed the same tasks as above, run full virus and spyware checks, latest MS Malicious software removal tool in full mode, scanned the services for suspects and stopped those that I knew I could do without. Next try maybe IrfTracker? Lots registry manager products make speedup claims which do not seemed to be supported by MS help systems, anyone out like to comment on that?

Re: PC Slow and runs at 100% cpu

Restating above – all input gratefully received. Darryl
