After upgrading a Windows 98 PC on a 2K network everything was fine. Authentication was good, login script runs and drives are mapped. I left and the user ran the automatic update. Now I can't get the users account to do anything but log into the domain. The server will not allow access to the resources. As admin it works but not the user. I have removed and reinstalled the user account, removed the updates, and nada. The user can log in from another WS and access the system (98). Come to think of it, I have had this problem with another upgrade in the same domain. Symptoms are extremely slow network access and slow logins. The other system authenticates to the local machine so the user can access the server. Any ideas?

Thanks- Dan
