Okay, it all started when the computer wouldn't turn on, it said that there was a problem (Missing or corrupt) file – windows\system32\config\system. So I located the disc, went into recovery and copied the file, deleted the original, then copied system.bak from repair – as per instructions. I then went to reboot and Windows started, but then an error popped up, Isuss.exe, saying that "when trying to update a password, this return status indicates that the value provided as the current password is not valid." The system then shuts down, restarts and goes through the same motions over and over.

So I went back into recovery but suddenly I can't get in because I don't have an administrator password.

There are upgrades that fix all these but what do you do when you can't even get into the system? I don't want to overwrite the hard drive just yet.

ANY help would be great.
