We use the Novell Client, and in the past with our Windows 2000 images and sysprep, this worked perfectly. Before I launch sysprep, I login to the workstation with a specific user account which I want to show up in the username field of the GINA on first boot for my users. With WinXP SysPrep, the username field comes up as Administrator regardless of what I last logged in as. I've tried using various combinations of RunOnce and Cmdlines.txt registry tweaks to set the registry key that remembers the last login name, but they always get overwritten with Administrator.

Is there a way for me to successfully set the default username that shows up on first boot after mini-setup – or a way for me to keep it from overwriting my last logged in user with Administrator?
