You might be able to do something with terminal services. One user uses the local desktop on the PC, and the other is uses a remote desktop on the file server.

Alternately, you can have them run a batch file that deletes their connections to the file server under the existing credentials, then re-establishes under their own. E.g. when user2 comes on:

```
net use x: /d
net use \\servername /d
net use x: \\server\share /user:user2@domain.com <password>
```

I don't believe you can have two users simultaneously connected to the server from the same workstation without getting a credentials conflict error (although TS does it all the time). Otherwise, you could set up user1 with one set of drives and user2 with a different set of drives, and have them connected simultaneously. Nor can you have two console sessions on the remote PC with different credentials and switch between them. I would be happy to hear that I am wrong and how to get either idea to work.
