I can't comment on brain farting (at least right now although I do my fair share of it) but it sounds like a bit of a misconception of how Group Policy is applied...

The GPO is split to Computer Configuration and User Configuration. The software installation and maintenance node under Computer Configuration is targeting computers. The OU structure that you mentioned is containers that contain users. Computer configuration applies to computers. So... if this is what you are experiencing you need to have the GPO applied to an OU that contains the target computer accounts. If you run an RSOP report you should see that computer settings are coming from GPOs that are higher than your computer object (placement in AD).

Could this be what you are seeing?
