Are those different users you used ever logon to the system before? Users who have logon before have their credential cached on the local system so they don't need any DC for authentication.

I checked that with a newly added "test" user. I could login without error and delay.

Check your DNS whether the DC can be resolved successfully?

Have you used RSOP (rsop.msc or from GPMC) to check whether the computer or user portion has any GPO applied? Or which is the winning GPO for them?

The domain gpos couldn't be applied but I cannot say which has been applied because I just reinstalled windows on that machine. Thank you for your effort anyway. Unfortunately this workstation needs to be working tomorrow so I haven't had another choice.

All I can tell is that I ran rsop.msc and saw that computer policies were applied but user policies not (red crossed symbol).
Again, thank you.

Christoph Kling
