True. In most cases where I have implemented restricted groups it has lasted a little while and then someone comes up and says, hey we want Bob to be a local admin on these 5 machines and not the rest and alice to be local admin only on her machine, etc..

Is your Domain Win2k? You could use a restricted groups policy, but I'm not sure that it works on Windows 2000.

It does, and the ability to use only the Member Of list also does if it is W2k Sp4.

However, I do not believe this is a viable solution. As I attempted to describe in other post this thread, using the Members list of restricted group definition replaces the complete and total membership on the impacted system. This is in my experience more often than not a non-useful capability as one often needs per-machine uniquenesses.

But you are correct, if poster simply wants to reset the membership of the machine local Administrators group on many machines to the exact same membership on them all, then yes, restricted groups would work for that purpose.

Roger

Here is an article that implies that it does <http://www.windowsecurity.com/articles/Using-Restricted-Groups.html>

## Re: localgroup administrators

I need to set a group policy to remove domain users and only add domain admins to local group administrators on workstations. Mixed xp and 2000 environment. W2k3 server. I am trying to use net localgroup administrators /add and /delete. Using a startup script with only test computers having read access. What variable can I use for the domain users, and will this work? Is there a script for this?
