I have set up an AD/AM server on our network to provide address book information for remote users. It works great for users that are connected to our campus network, but if you attempt to authenticate using the Windows Address Book from a computer that is not joined to the domain (or joined to a different domain) the authentication fails. There was some discussion on this in the Active Directory group here:

http://groups.google.com/group/microsoft.public.windows.server.active_directory/browse_frm/thread/b1c2a732a2b10

Let's say our domain is CAMPUS, and I have a user account named aaron (CAMPUS\aaron). If I'm logged in to my workstation here on campus and use Windows Address Book (WAB) to access the directory using my CAMPUS\aaron username/password, it works fine. But, if I go home and log in to my local home network with a domain of HOME, and then configure WAB on that machine to authenticate using the same CAMPUS\aaron username/password, WAB will instead use my HOME domain username and password in it's authentication INSTEAD of the username and password that I have told it to use.... I know this from looking at a packet dump of the traffic.

Anyone know what might cause this or what I can do to correct it?
