You will need to use ntdsutil to remove the orphaned dc/domain. Take a look at the following MS KB articles for instructions:

230306

216498

> *I'm having trouble with a non-existing domain controller/ad-domain. This time my fingers were faster than my brain...I formatted a domain controller's system partition since it wasn't no longer needed. It was the last domain controller in that child domain which was meant for testing purposes. Now the other domain controllers in our tree are still trying to replicate with it, because the domain was not correctly removed with dcpromo and the AD still thinks this child domain is there. How to correct this? I'd appreciate your help!*
