sI couldn't find a group dedicated specifically to AD question on Win 2000 server so i am going to post this question here...sorry

here's the scenario..

We currently have a web application that uses forms based authentication which is stored in a SQL server database....So user logs in, the username is validated against this sql database and then depending on their job function another set of rules and permissions stored in a different table are run for that particular user...

The business that use this application want to move the wuthentication peice of this app from SQL to AD but leave the permissions table in this SQL database...

So ideally, a user logs in, they are authenticated against AD and then the request is passed back to this SQL server where the validated username is matched against the same username in the table and then the appropriate permissions set are granted.

Is there anything out there that can do this?

The business do not want to move the permission set to AD coz it is huge and complicated and took them like 6 months to get right.

I know its a shot in the dark but is there anything out there that can achieve this?

many thanks for any help....
