Hi!

I just thought make a logon script that would add users to admin group.  
Enable user loopback policy mode in computer configuration. Our computers are in OUs containing only computers so I would link the policy to those OUs.

I was just wondering using such policy will it make difference who logs in and what is his group membership? Will it make any difference while using loopback policy?

Yes, I was also thinking about restricted groups, but I was wondering how to add users to local admin group for all desktop computers. Could it be possible using GPMC from workstation? And what would happen then when we are not using those groups any more? We should add account into local admin group somehow after that..?

Esa
