Does the following KB article help?

Yes, but I did the workaround in it, did a gpupdate /force – made sure it applied via rsop.msc, restarted the server and client, but I had the same error. So, I then undefined 'Network security: LAN manager authentication level' in the Default DC GPO, did the same steps above and still received the same error.

In my eventvwr on the server I see: Successful network logon: Username: userguy, domain: fallacy, logon type: 3, logon process: NtLmSsp, authentication package: NTLM, workstation name: \\TEST, source network address: 10.69.0.10, source port: 0.

In the same second the following appears in eventvwr: User Loggof: Username: userguy, domain: fallacy, logon type: 3.

Any other ideas? If I have to use the AD client for 9x, I will.
