These error messages indicate the Windows workstation or server computer account information does not match that held by the authenticating domain controller.

Solutions:

1. Reset the machine account by using the Active Directory. You can right-click the computer object in the Computers or appropriate container and then click Reset Account.
2. Remove and then re-join the computer from/to the domain.
3. Use Netdom.exe or Nltest.exe to reset security and trust relationship

- Are the machines only using their local DNS server?
- I already read that in some situations that the FW was responsible for this.

Hello M. Silva,

The security policy for these parameters are not set.  
I think he was logging out for the 2nd or the 3rd time.  
I don't think this was the cause. He has the same symptom that others  
workstations. With or without the network these workstation wasn't able  
to  
authenticate in the network.  
Usually we need to make a new ID for the workstation, going out of the  
domain and re-join the domain. This operation consume time for us and for  
users; and it's not a good solution having to make new ID's regularly.

Have you got other possible causes to tell me ?  
I will try to keep one workstation on my office next time it happens in  
order to investigate more symptoms. because i remember that domain  
administrator's login (which was the account used to join the domain) was  
able to login to the domain;  
Other symptom is : the SID of the account "administrateur" was visible in  
local SAM when viewing the administrator group.

thanks for your help.

Paul

Hi

How is the security policy on these Machines? By default (Assuming  
Windows  
2003) they're able to logon 10 times with no DC.  
"Interactive logon:Number of previous logons to cache (in case of no DC  
available)"  
also check:  
"Interactive logon:Require DC authentication to unlock workstation"

Hello everybody,

I have looked all around to get a solution about this event ID  
5719.  
This problem appears Monday 17/07/06, on a XP SP2 client;

My boss was at home and tried to log in (normal) and he got  
this event  
5719  
!!!!  
With no network at all windows tried to get a DC ??

For all, windows cache login information in order to let the  
user use  
his  
windows when he is not in the office. That wasn't the first  
time he  
logged  
in  
offline but for the first time he refused to log in. Any idea ?

Sometimes, some of users have the same symptoms in the  
company. Their  
configuration is well done, no LMHOST, no Wins. And last  
time, on  
monday  
morning 10 users has this symtom; they are on the network  
but we need  
to  
put  
them in a workgroup and re-join the domain. strange, no ?

On the system event log of the DC, some event ID 5513 but  
theses  
workstations haven't this problem.

Could anyone help me ?

Thanks,  
Paul Goncalves
