-

- 1) Change the local Administrator password to something difficult and never use it
 - 2) Use Group Policy Restricted Groups to add your IT Support guys to the local Administrators group with their normal account
 - 3) Do not give users Power User rights either. The IT Support guys should be able to do most things remotely
 - 4) Find out what the users think they need admin rights for, and work out how to get round it

is it possible to configure a script, gpo, or push something through AD, ldap, that will remove all permissions from the local administrators group of the machine and replace it with ones I want on there.

Basically we do not allow users to have local admin rights for obvious reasons. Instead we give them power users. "Somehow" I am seeing more and more that either the domain users group or the actual user is being applied to the local admin group of the computer.

Im sure it happens over there but some morons who work here have our admin password and their way of solving permissions/problems is just giving the users local admin rights! Frustrating!
