I've seen this problem with a remote domain that's linked with a trust and with one that has no trust relationship. I can map a drive from windows explorer or the command line to any other server here except the domain controllers in the remote domain. The network connectivity is good – either on the same subnet or connected by a hardware VPN. I use the ID of a domain admin to either an administrative share (C\$) or c:\test, or a domain user to c:\test, which is shared everyone:full control. All fail with "System error 5 has occurred. Access is denied."

Any suggestions?

Bob
