Currently we have a corporate office (with a datacenter) and a hosted DR site. We have two active domain controllers, one in the corp datacenter and one at the DR site. We are going to be adding a foreign satellite office soon. We are planning on adding a domain controller at the satellite office. I am looking for best practices on how to do the following:

1. Users at our CORP location do not ever go to the new Domain Controller at the satellite office for authentication.
2. Satellite office uses new Domain Controller for authentication, and then can see the CORP domain controller as a backup.
