thanks joe.

I think we will just make this a DC in our forrest/tree root domain. and create a site link, thanks.

i was erroneously trying to logon to the domain where the user account did not exist.

cheers

You need to ask yourself – Why do we need a child domain? If you can't answer this question it's likely you don't need one.

From the information that you have given I see no reason why you would need to create a child domain. I would proceed with making the server that you have a DC in your original domain and setup a Site for the Singapore subnet.

If you were to proceed with a child domain you would also require another server. Although you can run a domain with a single DC it is not recommended. There is also the obvious extra administration overhead of running two domains.

On your other point. You cannot logon to a domain with a user account from a different domain. You can however logon to your own domain from a computer in a different Trusted domain. When you tried logging on in the different domain did you select the domain that the user belongs to from the domain list?

Hi,

My organisation currently has one domain and several sites.

We are based in australia and have a new remote server in singapore, we are considering making this a child domain of our current domain, but are unsure if we should make it a child domain or just a DC of our current domain with a site link?

if we make it a child domain, and we have users in singapore on this child domain, can those users then come to our parent (forrest/tree root) domain and login with their user accounts created in ths singapore child domain, and vice versa?

I thought this was possible but i recreated this situation in a dev environment, creating a user in the parent domain, but that user was unable to login to the child domain!

any advice?

thanks
