Hi, Paul.

There is some revolution In my case. The main problem is accessing the network shares created on DC1. I can't get access to it form any computer in my network. And because of that I have the problem to access the SYSVOL and Netlogon default shares. That creates a whole range of errors in my AD environment. Even if I create a new Test share with the right permissions and security configuration I get the same error when accessing the share by typing its path with server name. That means that I can't access shares using path like this \\DC1\Testshare\ from any client/server that is a domain computer or even form the DC1 server itself when logged on by the console. I was trying to do that with the Administrator account. What is strange is that I can access this shares by the server IP Address and the share name (\\192.168.10.1\Testshare\). When typing it like this the access is granted and I can do everything that is permitted by the security to that share. I think this is something with security configuration but I don't now how to fix it.

In my physical network I have two Network services 1 is an AD Directory Service and 2 one is a workgroup. Both are in the same subnet range 192.168.10.0 /24. There is access to the computers form AD to WorkG and vice versa. And here comes the part that I really don't understand:

– When list the \\DC1\ from WorgG I am prompted to login. I write the user name and password and I !can access the computer (Server) and shares using names. This is what I need but;

– When trying this form the Domain computer or Domain server, there is something like this:

(There's access to server it self – shares appears on the screen without login prompt)

–Domain computer: when trying to open the share folder: I'm prompted to write user name and the password and this goes over and over again. The access is not granted.

Re: Sysvol issues.....

– Domain server logged in locally or by the console to the server that holds the share (DC1) when trying to open the share folder that appears on the screen there is a message:

“\\DC1\Testshare\ is not accessible. You may not have permission to use this network resource. Contact the administrator of this server to find out if you have access permissions.”

“It’s not possible to read information about the domain controller configuration, because the device is busy or the access is forbidden.” <– this is in other language so I have translate it the best I can.

P.S.

There are 2 DC in my AD environment. There are no problems like this with my second DC.

Help… And sorry for my bad English I’m trying the best I can.

I don't see a problem modifying the registry to force the client to broadcast mode. Once done, you may have to reboot (Not sure) but after the change try and see if you can get it to work.

The dc doesn't need to be a b–type for a client to find him.
