I'm attempting to set up a clustered network for an exchange 2003 server. I've successfully set up the system but I've noticed one discrepancy with the instructions set forth by microsoft. At the very of their guide they test the failover of the servers by using the "Move group" function of the right click menu in the cluster administrator application. My problem is that the instructions state to move "Disk Group 1", but the clustering setup software never created this group. Is this group set up by the user and not necessary for anything? Is there any data in the group that needs to be included? Does anyone have problems using the "Move group" function?

Here's the link to the guide I'm talking about, the testing phase starts on the bottom of page 21.
