Hi,

Last week we reconfigured our network to use subnets. After changing the subnet on our cluster, I'm experiencing the following problem. Both nodes seem to function properly, only one node is not able to host any virtual servers. I'm able to reach and use the resource when i'm in the same vlan, only other vlan's cannot reach the resource. When i move the group to the other node everything works fine. I've compared all the settings from both nodes, and they are as far as i can see exactly the same. we also have a second cluster which functions perfectly. The routing between vlan's works well, we've checked that.

hope i'm clear enough
