Is there a way to initiate zone transfers manually from the master DNS server in Windows? We don't have full access to the slave except through a control panel. Let me tell you why I ask.

We have a sever that is allowed to use our providers two DNS servers as slave. Basically you go into their control panel add a domain, select slave and enter your DNS servers IP address. We are running a Windows 2003 server with our own nameservers, we also added their nameservers on each DNS entry and have zone transferred enabled and only to servers listed on the nameservers tab. So basically we have four nameservers entered ours and theirs.

We added about 140 slave entries, but in the server events log it only showed two of them that transferred. I have deleted and re-added some just to check, but still nothing.

Any ideas as to what is going on?

Thanks in advance
