Hello,

I've bought a domain from a registrar and Internet broadband access and static IP address from my local ISP.

My site is accessible via IP, but then I asked the ISP to link my domain to the IP address and entered my ISP's DNS servers in my Registrar Account Manager. They told me that I should pay for providing services of "primary and secondary zones".

Question:

Is it technically possible to set up my Windows 2003 Server (having only static IP address) to server as both DNS server and HTTP Server and enter DNS information (names of primary and secondary name servers) in Registrar Account Manager ?

P.S. I know that both DNS server and IIS exist in 2003, I just want to know from your experience is it technically possible to do the thing I want (preferably without third-party applications). I need this to provide higher level of service availability for my customers in case of ISP change.

Yours sincerely,

Kostyantyn
