Hello,

Everyone in my LAN, started to have a problem browsing the internet. In one minute a lot of people get "this page can not be displayed" message from the browser, next minute it would be ok, or some times slow. The company who provide our IP and hosting service says, some of their DNS servers are over loaded, and I must add their caching server IP address.

My question is, where do I add the external DNS server IP address, so that all the user who login to Active Director have no problem with their browsing? (Ping, and IP based access to and from LAN is Ok, just browsing, all of sudden started to give problem.)

I have ns2, and ns3 records in my DNS—>Forward lookup zone, pointing to old (providers) DNS

I have 2 internal DNS servers (domain controllers), and all my workstations are logging into windows domain no problem.

Help is appreciated

MC
