All,

We have a growing problem in our networking environment and I can not find a concert solution for it so I need help. Problem is that I have a printing device set to DHCP somehow obtaining the servers static IP Address which is XXX.XXX.XXX.253. How is this possible???? The server event log shows TCP/IP errors stating that there is an IP conflict on the network with the follow MAC address and the MAC address is the printer. This should not be happening. My only guess and this is a long shot is that although the .253 address is excluded from the DHCP Scope, it is still set in the distribution list and that how the printer temporally got static .243 addresses. Any help would be welcome..

DHCP Scope setup with a IP Address range of XXX.1 – XXX.253 for distribution and then I have an excluded range setup from XXX.196 – XXX.253

Logical Printer: 1 SHARP Photocopier by FEI

Routers: 1

LAN Switches: 2

Size of network: 50 users

Thanks,  
jthomas129

Not really anything to do with DNS and would suggest the m.p.w.s.general or a networking group for this next time, but just create a DHCP reservation for your printer(s).
