I have a serious problem with one of our servers that had the following autoupdates applied. In order of first to last. KB835732, KB828741, KB837001, KB840374, KB832894, KB837009. The server was restarted and all was fine until....a developer removed all of them in one fine foul swoop and then restarted the server avoiding the mandatory restart in between the required updates. The problem is that by doing this there have been several file version renamed incorrectly because of this. How to I hack the registry to avoid a blue screen on another box the developer has done this on. Luckily I managed to stop the plonker before he trashed my entire network.

Slightly devastated
