We have a hub and spoke (or branch office) Active Directory infrastructure with over a hundred remote sites in one domain. I have been migrated the sites from NT 4.0 into one Windows 2003 domain. I have recently migrated one of sites (a very large one) with two class C subnets. I have only one domain controller though (for now) that resides on one of the subnets. I need to make sure that both Win98 (with DSClient installed) and WinXP clients on the other subnet (without a DC) do not try to authenticate to any of the servers in the central office (the hub) but that they all connect to the local DC that is on the other subnet. Can I define the logon server either by IP address or by name? Is there a registry setting that I could modify or add, to allow me to specify the DC for Win98 and WinXP clients to log into?
