Slow login due to group participation

I have a client who's on a new terminal server, and it runs great but if someone's in a particular group, the logon takes about 3 minutes. if they aren't added to this single security group, login is instantaneous.

This group (companyname_users) is a securtiy group that has no group policy objects applied to it. This group in question is a member of 37 other security groups. They're using it to simplify their role group management.

Is there some way to determine where exactly the problem lies short of removing those 37 groups one at a time, test to see if that was the problem, add it back, and move to the next one?

Anyone have an easy way to help track down just where the delay is because of the group membership?

Thanks for any suggestions.
