Demoting the server did not help.

The last successful startup I have with log entries I expect logged the following service startups:

- Terminal Services sent a start control
- Network Location Awareness sent a start control
- Network Location Awareness entered running state
- Terminal Services entered running state
- Network Connections sent a start control
- Network Connections entered running state
- Windows Installer sent a start control
- Windows Installer entered running state

The last service item logged before I restarted after running DCPRMO was the File Replication Service entered a running state. Only error prior to the restart, is a w32time error (The time provider NtpClient cannot determine whether the response received from svrhank.newhome.domain has a valid signature. The response will be ignored. The error was: The interface is unknown. (0x800706B5))

There are no errors after restart, just a warning that my DHCP service doesn't have credentials to update DNS.
