If the permissions are for domain admins and you are using a local admin account that is not a member of the domain admins group then something else is happening..

Do you have the same password for local administrator and for domain administrator?

There is also ownership rights of file and directories so if all access rights are removed then the owner can amend.

Hi,

Could anyone advise on general good practice security permissions to set for general file shares.

Our system typically has the following settings:

- At the share level, 'everyone' has change permissions
- At the security level, specific settings applied to domain security groups

I have just noticed that when logged in locally to a pc as local admin, which is joined to the domain, I can create and delete files and folders despite the folder security being set to domain users read, domain admins full control?

am i doing something wrong?
