Hello,

I am not a Windows server guru by any means; I was thrown into this position and had to play the "figure out yourself game for six months now" I am at a school that has AD setup and has two groups of users...students and faculty....both are just set up as domain users and users. The problem I have is a strange one...One of the technical assistants had to reinstall Windows on the hard drive of a previously crashed computer. She joined the computer to the domain using the admin account; and installed all of the programs necessary for the faculty member to have. The problem is, when the faculty member logs in and tries to run her programs, it says she does not have sufficient rights to do so. Before her hard drive crashed, she did not have any special privileges that would give her any extra authority to run stuff on her machine. Her account is setup just as all of the faculty members are setup and none of the other members have trouble running their programs...I even deleted her account and copied one of the other members accounts so that everything was identical; Still no success; she cannot run any of her programs on her local machine without getting the message of insufficient privileges...Temporarily, I made her a member of the Domain Admins group to circumvent this, but this is not how I want things to be set up...(security nightmare)...So based off of the info, is there anyone that knows where I can look to fix this issue?

Thank you in advance for your time.

.
