You could try a NET USE * /delete to delete all his currently remembered connections.

Another thing that would prob work is to temporarily create a mapped drive to the share using the "connect using a different user name" option and make sure to put the correct info here, mapping this even just once with the right credentials and then disconnecting the drive would fix the permissions issue.

Hi,

I have a Windows 2003 server with 30+ domain users. I have shared a number of folders on the server for these users to access and store files, however, there is a laptop which does not logon to the domain, but exists on the network.

Normally, I would expect a username/password prompt to show if this laptop were to access the Win2003 server's shared folders. This did occur a few times, but has now stopped and keeps prompting the same message of having no permissions to access the resource. How do I continue to have this username/password dialog appear?

Thank you in advance,

A.
