Hello everyone,

I'm planning to move my domain controller responsibilities from two antiquated Win2k DC's to some new servers that will be running Win2k3, then retiring the two old boxes. I've been reading up as much as I can on this, but do have a question inre to the ADPREP commands that I need to run.

The documentation states that one needs to run ADPREP /FORESTPREP then ADPREP /DOMAINPREP before proceeding further. It states that you should only run this once however, implying that bad things happen if you do this more than once. The problem is that I believe I ran these same commands when I upgraded my Exchange 2000 serer to Exchange 2003 (It's still running Windows 2000), but can't remember for sure. Is there a command or a switch to the ADPREP command that will allow me to check to see if my schema has already been updated?
