Hi

When we create socket for server , first we use SOCKET () then we will Bind () to the port .

what is the use of this kind of mechanism .

If u compare this with file opening . why not fopen() used then it will Bind() with file name ..?

we use only one statement to open file , But why we use two statement to open socket connection..

(why can't we provide port , server structure in socket.) .

why they designed like that ...?

Please clear me..

Thanks
