Right. When you connect, check that the dd interface status has changed to "connected". Then do a route print on both servers. The routes you linked to the dd interfaces should have been added to the routing tables.

If the routes you set up were correct, each router now has a subnet route to the "other" site through the VPN tunnel. Every machine in either site should be able to ping any machine in the other site. The VPN routers are the default routers for each subnet?
