Mr Grant,

You're saying that 'domain\username' and username@domain are interchangeable? For example, "terry\vlad" is the same as "ronin@vlad" when logging into a Vista machine in a corporate environment? The 'username@domain' will probably be a little easier for most to remember, since it's akin to typing one's email address. The '.local' you mention is not necessary in the domain\username syntax. Are you saying, in the username@domain syntax, it should read something like ronin@xxxxxxx?

It's my understanding that logging into a local machine, that is part of a domain, is not like logging into a standalone computer. If the user does not have a local account setup on the domain-connected computer, that user will not be able to log into it locally? If this is true, that would be great.

"Bill Grant" wrote:

Once a machine is joined to a domain you should have at least two options available in the logon dialog box. If it is showing the local computer option you enter your local username /password and do a local login. If the domain name is showing you enter the domain username/password and log into the domain.

If you are at the local machine login and you want to log into the domain you can enter your username in the user@xxxxxxxxxxx format to do a domain login.

My issue kind of starts where your issue ended. Now that you're able to log in to your work domain, do you have to input the domain\username syntax? If

Re: Why am I always prompted for name/pwd when accessing domain re

not, how did you overcome it? If so, is there a way to change this so
users
can just enter their username and password?

Thanks! I actually ended up taking a more
manual approach...exposing
hidden
folders, copying files from
c:\users\<profile1> to c:\users\<profile2>,
etc.
I definitely like the idea of your approach
better. I don't like doing
too
much "under the covers" if I can help it. But
so far it still seems
stable
and like it's working okay.

Thanks for the response,

David

File and Settings Transfer
Wizard

At least that was what they
called it in XP. It may have
a new name
in
Vista,...not sure

1. Log in with local account
first. Use the Tool to save
the user
profile.

2. Log in with the domain
account. Use the Tool to
import the profile
previously
saved allowing it to over
write the existing domain
account profile.

I'm going to
keep
replying to
myself as I
get more
information.

If I go to
System
Properties,
and then

Re: Why am I always prompted for name/pwd when accessing domain re

Advanced
System
Settings,
and
click
on the
Settings
button in
the User
Profiles
section, I
can see the
two user
profiles.
There is a
very
convenient
little "Copy
To" button
that
appears
to
be for
copying a
profile from
one account
to another.
Unfortunately,
it's
grayed out.

Note that I
don't have
roaming
profiles
setup on
this
domain...all
profiles
are
local-only.

Thanks,

David
