Okay, finally did it, just like everyone said I should.

Now here is the deal, the server can access the internet, but only certain sites for some odd reason. All computers are the network cannot access the internet at all.

So, what gives? I set up the whole network per the "Two Nics, a static IP address, ISA, router" @ smallserver.net And nothing is working....

Also, per the setup, can I only access the router config on the server? Or is there a way to jump nics to see the router from a workstation on the internal network?

Thanks!
