You are going to have to take a multi-layer approach to this (well at least I would).

- 1) Change all the Admin passwords (servers, routers, workstations, etc.)
- 2) Change the password on his/her his former account and disable it.
- 3) Audit the systems in step #1 to make sure that there are no other admin accounts that the person can get access to. If there are and you need the account then change the passwords. If the account is not really needed then change the password and disable it.
- 4) Audit the systems again – make sure that there are no logging systems that might be potentially relaying your password changes to the former admin on a remote account, if you find any then start at step #1 again.
- 5) Change the users accounts on the domain to force a password change at the next login. If he/she know any user passwords this will negate them any other possible access.
- 6) Continually audit your systems – if you are an admin you should be doing this on a regular basis anyways.

I am sure that I missed something so I hope that any other ideas are passed along to you by other ppl on this group.

Carlos
