Hi group,

Just got at SBS2003 up and running on a Dell PE2800 (nice piece of HW by the way). I've got a problem with a specific remote client, that is connected to the network through with Cisco Client to some Cisco box – no problem. The machine is not a member of the domain, although local credentials equals the credentials for the corresponding domain account. The problem is that when I create a profile in Outlook for this particular user on this particular workstation, when I'm able to login without any problems – the first time. Any subsequent retries, Outlook just states that it's not able to connect to the server. Tried:

- restarting the client
- other machines → no problem
- added the SBS2003 to the hosts file

This very machine worked flawlessly on the old SBS 4.5 server. Anyone got a clue on this one?
