I have a new SBS2003 SP1 premium installation. ISA is setup with two NICs and I haven't made any changes to ISA. The client machines (only 2 so far) use DHCP and are able to reach the //server website and when I added the firewall client can connect to any Internet sites. The client machines point to the SBS internal IP for DNS and gateway.

I can open the <http://companyweb> site on the SBS. When I try to open <http://companyweb> on a client IE gives a "cannot find server or DNS error". I can browse to //server and open RWW , connect computer or information and answers.

As a test I added an entry of <server IP> companyweb to the hosts file and IE was then able to open the sharepoint site. So it seems like a DNS issue but I don't know where to look.

Any suggestions appreciated.
