Support showed me what registry keys to change on the client to make the connect. What the heck, it doesn't matter that I selected 8085 once in the past. I can certainly remember the new port number.

Now to turn off the SSL requirement. What is really strange about the use of SSL, is that it is only used for the server console. The client computers don't use it. One needs encryption between the keyboard processor dll and the OfficeScan login page? Just how many people are really afraid of little people sitting inside their mainboards to steal keystrokes? Frankly, I find the password a real pain, as I have been manually updating every few days. (That came about when their automatic download code failed, and then changed the service account from domain administrator to network. It took them 6 weeks to track that down. I have never really trusted their code since.)
