try creating the uses via the sbs add new user wizard then adjust the group that they are members of then log in remotely and see what happens.

I have a SBS 2k3 std server with a working VPN.

I would like to give some customers accounts to have their own e-mail addresses and a place to dump files for use that only they can access.

The most important issue here is getting files to and from the clients with no size constraint. I would consider using FTP, but I would like to use the file transfer method over a VPN since this would also allow for printing and other shared resources.

Because these are outside people I do not want them to see ANY share on the server other than the one they have access to.

I tried setting a new security group called "customers" and added it to each share setting permissions to deny. I also went to each folder and changed the permission at the folder to deny listing folder contents.

I created a new user using Active Directory Users and computers (not the SBS tool, but should still work fine). After setting up their account, I changed two options three items in the account properties.

- 1) Change logon-to option to say "only selected computers" and I left the list blank (this should stop them from any local login)
- 2) Changed the remote login policy to allow (from let Routing and Remote Access determine)
- 3) Removed the user from the Domain User group and added them to the customers group.

They are ONLY in the customers group and should now only have access to the one folder I did not specifically deny the group access to.

I am working remotely, so I logged off my account and reconnected using the test customer account.

Re: User Share Permissions NOT WORKING!

To my surprise, I found that I had COMPLETE access to EVERY network share.

I logging off and logging on again, I verified that the settings were what I described above and applied. Everything seems to be in order, but the permissions do not follow what is showing for each shared folder.

I now have to go through every user account to make sure that employees don't have access to things they shouldn't have access to.

Anybody know what's going on?
