I'm just beginning to add items to Sharepoint, not more than 50 docs have been uploaded on 3 subsites.

As for updates, I've been good about using WSUS. I've got it set to get updates every night so I can check it in the morning and pick which ones apply and then download and install them. The server is current as of Thursday last week.

The only other Event ID's in the DNS log are 708 and 4001.

Mike

Hi Mike,

recovering Data is fine, recovering exchange is fine (we holding your hand..lol) but you just put a damper on (from personal experiance...sharepoint..ouch) I personally haven't tried restoring sharepoint and some have had issues.... how much data is here / how critical is it... just asking incase better to input details again manually. Dont want a sharepoint restore messing a fresh install...lol

With your current issues, have you applied ALL updates to this server ?

Me personally I do not like trying to fix a broken server, you fix one thing, all seems fine and couple weeks down the road issues again, you fight 2 avenues, is it something recently or to do with previous issue.

Add to check list, once installed apply all updates before trying to recover data...lol

MS article 316685 problem with DNS I have seen when permissions on certain folders haven't restored properly.

There must be another error in logs related to your problems I dont think this article is related to your probs... Just checking, have all service packs been applied?

It's running, but I had it on Manual. I'll put it on Automatic right now.

Check to see if the Kerberos Key Distribution Center service
is
started,if
not
start it and set it to Automatic.
