By cant access, I mean that the computers cant ping anything including the server. My DHCP server is not leasing any addresses to the computers. All the computers are personal computers that were preconfigured with Windows XP, So correct, the server was set up after all these computers. Also what do you mean by the IP config properties. How do you get those properties where I can remove the DNS suffix. I can take a snapshot of the IPCONFIG on either computer and e-mail it (Can I post a picture on here?)

Were these computers previously configured without your SBS server in the picture? In each computer's IP config properties (DNS / advanced) remove the connection-specific DNS suffix or anything that says RCN (or is statically set).

That said: you didn't really describe what "can't access" means. Can you ping the router's LAN IP? Can you ping a public DNS server IP address? Can you ping www.google.com from a workstation?

Try posting an unedited ipconfig /all from the server and from a recalcitrant workstation in here.
