I have a IP Address via a T-1 to my Router, then I have a LinkSYS plugged into the T-1 Router.

The x.x.x.100 Ip address is a public IP address, which then is Natted via the Linksys to the internal network.

Internally I have 192.168.100.4 for the external card and 192.168.100.7 for the internal card.

I dont care much for ISA server, the Linksys does everything I need to do.

My question is,

should I change the NAT IP address from the LINKSYS to a different internal IP range for the external card (SBS) and match it to the external card, it does not seem right to have both the internal and external on the same subnet.

Then Should I point all the workstations and other server(s) to the internal IP address as the gateway (NIC on the SBS called internal)?

Then uninstall ISA, and all should be well...correct?

I have SBS Premium R2..THANKS!
