

## Re: Ownership and Rights

I have a partition that is set up for all of the shares... and the shares are set up to reflect the original Novell Server. The share that I'm working on has share rights of Everyone, Full control... obviously not a long term solution, but for now I just want it to work.

Everyone = full control is fine, for the share. A lot of people leave their share permissions wide open that way. They will be trumped/superseded by the NTFS permissions.

There are a number of other rights set up on this folder, but currently Everyone, Full Control is specifically set, and rights are inheritable in the folder.

For NTFS, or for the share? The latter is what really matters.

I've implemented a SBS 2003 in a small Land Surveying company... I migrated their data via backup over from Novell, and the entire server seems to work well.

The problem is a rights problem. I have defined a Security Group that all the drafts people are part of, and sharing files works fine, except when a person

## Re: Ownership and Rights

makes a new file. They are the owner by default, and no one can access the file on the share until I force ownership to Administrator or to one of the other users. Once I've forced ownership, the shared file works fine. Even when I browse to the file on the server to check ownership, I am forced to take ownership before I can do anything with the file. Obviously this is not a workable scenario... I can't tell the users... "OK, here's how it works, make a new file, then call the Network Admin and have him change the rights on the file, and voila, it'll be sharable." I'm a tad frustrated.

Why does this happen? Is there a default policy somewhere that precludes others from seeing the file? I can accept that the ID10T problem is sitting in my chair, but I simply can't seem to find resolution.

Ownership shouldn't make a lick of difference here.

Where's the folder? What're the share permissions, and what are the NTFS permissions explicitly set and/or inherited from the parent?
