We are running Small Bus Server 2000. I was told to post this question here as I may get a better response than on the SBS 2000 newsgroup...

I have a roaming profile issue that I would like some clarification on...

I recently set up a new user and forgot to enter the path to the roaming profile in his AD profile before logging him into one of our XP machines he will be using for the first time. While I was logged on I proceeded to configure his desktop the way he needs and when I finished, I remembered that I had forgotten to set up the roaming part of his profile. So before logging him out, I added the path to his roaming profile in his AD profile, saved it, and then logged him out of the XP machine.

I then went over to a different XP machine and logged him in to test, and behold, the desktop changes I had made on the previous login were all there – so I knew the roaming profile was working. I did not have to configure any printers on his profile as the various network printers he needed were already installed on that PC and as such existed in his profile of the PC he was logged onto.

Now this is where it gets tricky... Yesterday he had to log back into the PC I had initially set him up on, and some of the printers are missing – yet they are all installed on that PC because the main user of that PC uses them all the time. My question is, if the drivers are all installed on the PC, then why wouldn't all of the printers show up in his profile based on his roaming profile settings? Are printers not a part of the roaming profile at all? (I believe they are) – and even if they are not, why would all of the installed network printers not show up anyway – when they are all installed on that PC? Some of them show up and some don't!!

Help!

Thanks, Brad
