Hi:

Following is my current set up:

Domain : whatever.com.mx

Web page: hosted in another server (www.whatever.com.mx)

SBS server runs our mail server (mail.whatever.com.mx) and our rww (sbs.whatever.com.mx)

ADSL line with static IP (cost USD100.00/month no wonder why Carlos Slim is the richest man on earth)

DNS services: easydns

Smart host services: provided by TZO

Linksys router WRT54G TZO capable:

Objective: Cut the cost for the static IP by using a dynamic IP using TZO

I have purchased premier DDNS and a subdomain service to TZO.

I would like to beam both sub domains (rww.whatever.com.mx and mail.whatever.com.mx) and register both of them at TZO

also I want to wildcard whatever.com.mx to www.whatever.com.mx.

Questions:

- a) Can I do this using just the router firmware?
- b) What settings do I have to establish in TZO to make it work?
- c) Should I buy another subdomain service for rww.whatever.com.mx?

I have tried to contact TZO, but my english is not as I would like to be.

Any pointers are more than welcome.

TIA

Miguel
